## # i 3 more variables: voice <dbl+lbl>, trust <dbl+lbl>, male <dbl+lbl>
```

Simplify data

Here we apply some simplifications on data - i) Here we keep only observations with no missings (this is not the right procedure to deal with missings of course :-)) - ii) We focus on a subsample of countries (#360 Romania 255 Germany 380 Sweden 230 Spain)

```
value <- value[complete.cases(value),]
included_countries <- c(360,255,380,230)
value <- value[which(value$cow %in% included_countries),]
value$cow <- as.factor(value$cow)
levels(value$cow) <- c("Spain", "Germany", "Romania", "Sweeden")</pre>
```

Inspect variables

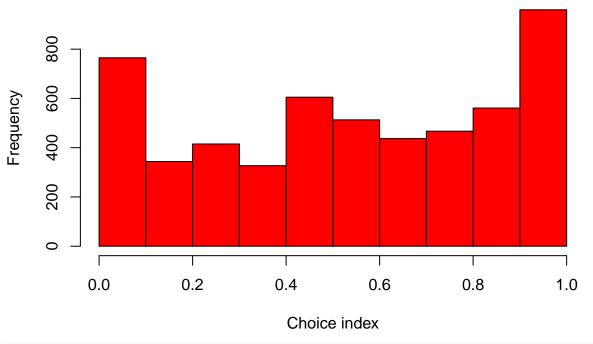

```
quantitative_variables <- c("lifesat", "age", "relativism", "scepticism", "equality", "choice", "voice")
dummies <- c( "male", "trust")
factors <- c("cow", "education")
qualitative_variables <- c(dummies, factors)</pre>
```

Look at the distribution of the Choice vari

ble

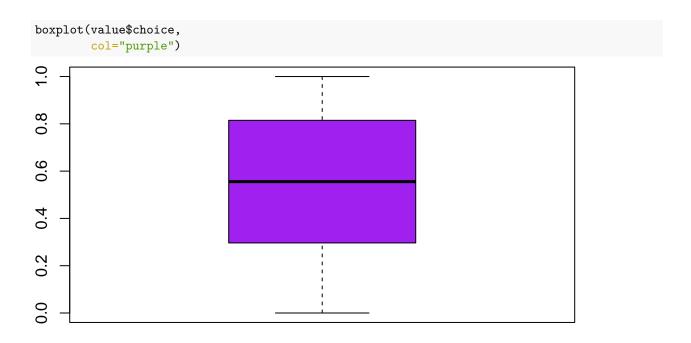

```
hist(value$choice,
    main ="Histogram of Choice Index",
    col = "red",
    xlab = "Choice index")
```

Histogram of Choice Index

```
summary(value$choice)
```

```
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.0000 0.2963 0.5556 0.5364 0.8148 1.0000
```

Hypothesis testing for one sample

Compute sample mean

```
sample.mean <- mean(value$choice)
print(sample.mean)</pre>
```

[1] 0.5363864

##

Compute sample variance

data: value\$choice

```

Let's pretend we have information about the population variance of the choice index. Let's say we know this is equal to 0.10. We can test the hypothesis that the mean of the choice index is equal than 0.7 using the z score.

```
alpha = 0.05
z.test(value$choice,
       mu = 0,
       sigma.x = 0.1,
       alternative = "two.sided",
       conf.level = 1 - alpha)
##

## 0.5337177 0.5390550
## sample estimates:
## mean of x
## 0.5363864
```

Hypothesis testing to compare two samples

Let's focus on two countries: Germany and Romania. We want to test some hypothesis about the difference im the mean choice index in the two countries.

Compute all the quantities you need

```
n1 <- length(which(value$cow == "Germany"))
xbar1 <- mean(value$choice[which(value$cow == "Germany")])
s1 <- var(value$choice[which(value$cow == "Germany")])

xbar1

## [1] 0.5322901

s1

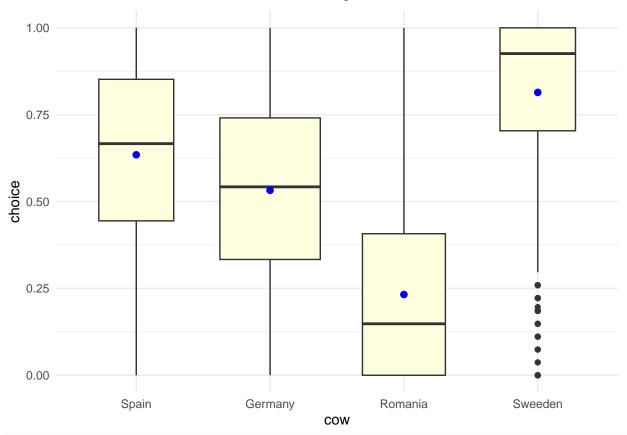

## [1] 0.0763298

n2 <- length(which(value$cow == "Romania"))
xbar2 <- mean(value$choice[which(value$cow == "Romania")])
s2 <- var(value$choice[which(value$cow == "Romania")])</pre>
xbar2
```

```
## [1] 0.2323472
s2
## [1] 0.06763639
Define a subset of the initial dataset that includes only observations from Romania and Germanua
value_gr <- value[which(value$cow %in% c("Romania", "Germany")),]</pre>
Test the hypothesis that the mean of choice is equal in the two countries (two sided test)
alpha = 0.05
t.test(value gr$choice[which(value gr$cow == "Germany")],
       value_gr$choice[which(value_gr$cow == "Romania")],
       mu = 0,
       alternative = "two.sided",
       conf.level = 1 - alpha)
##

Test the hypothesis that the difference in proportion of trust is greater in Germany (one sided test)
alpha = 0.05
prop.test(x = c(success1, success2),
          n = c(n1,n2),
          alternative = "greater",
          conf.level = 1 - alpha,
          correct = FALSE)
##
    2-sample test for equality of proportions without continuity correction
##
## data: c(success1, success2) out of c(n1, n2)
## X-squared = 498.38, df = 1, p-value < 2.2e-16
## alternative hypothesis: greater
## 95 percent confidence interval:
## 0.3386176 1.0000000

## 0.43057722 0.07006855
```

Test for variance (one sample)

We now focus on variances and we analyze the variance of the equality index. We test whether it is equal to 0.1 by using a chi-square test

```
varTest(as.numeric(value$equality),
        alternative = "two.sided",
        conf.level = 0.95,
        sigma.squared = 0.1
##
## Results of Hypothesis Test
## -----
##
## Null Hypothesis:
                                   variance = 0.1
##
## Alternative Hypothesis:
                                   True variance is not equal to 0.1
##
## Test Name:
                                   Chi-Squared Test on Variance
##
                                   variance = 0.06175685
## Estimated Parameter(s):
## Data:
                                   as.numeric(value$equality)
##
## Test Statistic:
                                   Chi-Squared = 3330.547
## Test Statistic Parameter:
                                   df = 5393
##
## P-value:
                                   1.101022e-118
## 95% Confidence Interval:
                                   LCL = 0.05949062
                                   UCL = 0.06415574
##
Now we test whether it is smaller than 0.1
varTest(as.numeric(value$equality),
        alternative = "greater",
        conf.level = 0.95,
        sigma.squared = 0.1
## Results of Hypothesis Test
## -----
## Null Hypothesis:
                                   variance = 0.1

                                   df = 5393
##
```

```
## P-value: 1
##
## 95% Confidence Interval: LCL = 0.05984857
## UCL = Inf
```

Test for variance (two samples

##

0.7827391

We want to compare the variance of the equality index in Germany and the variance of the equality test in Romania. We use an F test.

First, we test whether the variance of the equality in Germany is equal than the one estimated in Romania.

```
var.test(x = as.numeric(value$equality[which(value$cow == "Germany")]),
          y = as.numeric(value$equality[which(value$cow == "Romania")]),
          conf.level = 0.95,
          ratio = 1
##
## F test to compare two variances
##
## data: as.numeric(value$equality[which(value$cow == "Germany")]) and as.numeric(value$equality[which
## F = 0.78274, num df = 1922, denom df = 1312, p-value = 1.112e-06
## alternative hypothesis: true ratio of variances is not equal to 1
## 95 percent confidence interval:
## 0.7084131 0.8640485
## sample estimates:
## ratio of variances
##
            0.7827391
Now, we test whether it is greater
var.test(x = as.numeric(value$equality[which(value$cow == "Germany")]),
          y = as.numeric(value$equality[which(value$cow == "Romania")]),
          conf.level = 0.95,
          ratio = 1,
          alternative = "less"
##
## F test to compare two variances
## data: as.numeric(value$equality[which(value$cow == "Germany")]) and as.numeric(value$equality[which
## F = 0.78274, num df = 1922, denom df = 1312, p-value = 5.562e-07
## alternative hypothesis: true ratio of variances is less than 1
## 95 percent confidence interval:
## 0.0000000 0.8504372
## sample estimates:
## ratio of variances
```
